ABSTRACT

Objective The aim of this study was to investigate co-located nasal Staphylococcus aureus and coagulase-negative staphylococci (CoNS) (mainly Staphylococcus epidermidis), recovered from healthy medical students in their preclinical year, prior to exposure to the healthcare environment, for the carriage of genes and genetic elements common to both species and that may contribute to S. aureus and methicillin-resistant S. aureus (MRSA) evolution.

Design Prospective observational cross-sectional study. Carriage of antimicrobial resistance and virulence-associated genes in the absence of significant antibiotic selective pressure was investigated among healthy medical students from geographically diverse origins who were nasally co-colonised with S. aureus and CoNS. Clonal lineages of S. aureus isolates were determined.

Setting/participants Dublin-based international undergraduate medical students.

Results Nasal S. aureus carriage was identified in 137/444 (30.8%) students of whom nine (6.6%) carried MRSA (ST59-MRSA-IV (6/9), CC1-MRSA-V-SCCfus (3/9)). The genes mecA, fusB, ileS2, qacA/qacC and the arginine catabolic mobile element-arc were detected among colonising nasal staphylococci and had a significantly greater association with CoNS than S. aureus. The rate of co-carriage of any of these genes in S. aureus/CoNS pairs recovered from the same individual was <1%.

Conclusions The relatively high prevalence of these genes among CoNS of the healthy human flora in the absence of significant antibiotic selective pressure is of interest. Further research is required to determine what factors are involved and whether these are modifiable to help prevent the emergence and spread of antibiotic resistance among staphylococci.

INTRODUCTION

Staphylococcus aureus and S. epidermidis are significant colonisers of healthy human skin and nares and are among the leading causes of healthcare-associated infection. Morbidity, mortality and the financial burden associated with methicillin-resistant S. aureus (MRSA) infections are well documented. Furthermore, coagulase-negative staphylococci (CoNS) including S. epidermidis are reported reservoirs of antimicrobial-resistance genes and their associated mobile genetic elements, most notably the staphylococcal cassette chromosome (SCC) harbouring the mec gene (SCCmec).
Twelve SCCmec types and numerous subtypes have been described among MRSA isolates to date. The more prevalent and diverse range of SCCs and SCCmec among CoNS further supports CoNS as a reservoir for antimicrobial resistance genes. The identification of SCC, SCCmec and SCC-associated elements with other antimicrobial and virulence genes and their epidemiological relationships among clinical staphylococci has advanced our understanding of the role of CoNS in the evolution of MRSA. For example, the fusidic acid resistance gene fusC is associated with SCCmec IV-SCC476 and other SCC-like elements have been identified in S. aureus, MRSA and CoNS and may contribute to MRSA emergence in countries with significant fusidic acid usage. Furthermore, the SCC-like arginine catabolic mobile element (ACME), which enhances acid tolerance, is abundant among clinical CoNS isolates, in particular S. epidermidis and S. haemolyticus. Among S. aureus, ACME has mainly been detected among isolates of the community-associated (CA) USA300 clone. CoNS are also a putative reservoir of the high-level mupirocin resistance encoding gene ildS2, which is also increasing among S. aureus/MRSA in healthcare and community environments related to horizontal gene transfer or expansion of specific clones.

Increasingly, MRSA clones previously associated with the community such as clonal complex (CC) 1 are spreading to healthcare settings making the differentiation between healthcare-associated (HA) MRSA and CA-MRSA unclear. Therefore, detailed investigation of the genetic and phenotypic traits of colonising staphylococcal species in community settings is important to identify those with features that may contribute to their evolution into potentially successful and formidable HA clones. The aim of this study was to investigate co-located nasal S. aureus and CoNS (mainly S. epidermidis) recovered from healthy medical students in their preclinical year, prior to exposure to the healthcare environment, for the carriage of genes and genetic elements common to both species and that may contribute to S. aureus and MRSA evolution.

METHODS

Study setting, participants and sample collection

This observational cross-sectional study was conducted at the Royal College of Surgeons in Ireland (RCSI) from December 2014 to January 2016. Nasal swabs (eSwab, Copan, Italy) were collected anonymously from undergraduate medical students. Eligible students were those attending the RCSI medical centre to submit a swab for mandatory MRSA screening in the week before they began their clinical attachments. In total, 444/450 eligible medical students (250 (56.3%) men, 194 (43.7%) women) participated in this study. All participants reported no previous hospital contact in the 6 weeks prior to recruitment. The student volunteers were from the second year of the undergraduate medical programme and, as such, all participants were domiciled in Ireland for a minimum of 2 years prior to recruitment. Data were collected anonymously from each participant, including age range, region of origin and previous healthcare contact. Ethical approval (approval number REC949) was obtained and informed consent was obtained from each participant.

Sample preparation

Swabs were processed to recover S. aureus (including MRSA) and pathogenic CoNS species using a modification of a published method. Swabs were enriched in brain heart infusion (BHI) supplemented with 6% (w/v) NaCl for 24 hours at 37°C followed by further enrichment in mannitol salt broth for 24 hours at 37°C. The enriched culture was diluted 1/1000 and 100 µL was spread onto SASelect agar (Bio-Rad, Hercules, California, USA). Plates that yielded pink/orange colonies (presumptive S. aureus) were inspected for growth of colonies of relevant CoNS based on colony colour (e.g., light pink colonies of various sizes, presumptive S. epidermidis; white/yellow colonies, S. haemolyticus, S. hominis, S. capitis, S. warneri, S. caprae, S. lugdunensis). Presumptive CoNS species and S. aureus were subcultured from these plates onto Columbia blood agar and identified by matrix-assisted laser desorption/ionisation (MALDI)–time-of-flight mass spectrometry using a MALDI Biotyper (Microflex LT, Bruker). Matched isolates (where S. aureus and a CoNS species were recovered from the same swab) were cryopreserved and stored at −20°C (Protect bacterial preserver beads (Technical Service Consultants, UK)).

Characterisation of S. aureus and CoNS isolates

Genomic DNA from S. aureus and CoNS isolates was extracted using enzymatic lysis using the buffers and solutions provided with the S. aureus Genotyping Kit 2.0 (Alere Technologies GmbH, Jena, Germany) and a DNeasy Blood and Tissue kit (Qiagen, Crawley, UK). Genetic characterisation of isolates was undertaken by DNA microarray profiling using the S. aureus Genotyping Kit 2.0 (Alere Technologies GmbH) as described previously. The kit detects 333 gene targets including staphylococcal antimicrobial-resistance, virulence, SCCmec and ACME-arc genes and assigns S. aureus isolates to multi-locus sequence type (ST) or GGs. MRSA phenotype was confirmed in S. aureus and CoNS isolates positive for mecA by growth of pink (S. aureus) or colourless/white (CoNS) colonies on MRSASelect agar (Bio-Rad). When required, confirmation of carriage of fusidic acid resistance genes fusC, fusB and toxic shock syndrome toxin gene (tstI) were confirmed by PCR using the primers and conditions described by O’Neill et al. and Chen et al.

Fusidic acid susceptibility testing

Fusidic acid MICs (Minimum Inhibitory Concentrations) were determined by ETEST (bioMérieux, Marcy-l’Etoile, France) according to manufacturer’s instructions. Thirty S. aureus and CoNS isolates harbouring fusC or fusB were sub cultured twice before testing. Results were interpreted...
resistance to β-lactams and fusidic acid. The most common SCCmec type among nasal MRSA (n=9) and MR-CoNS (n=18) was SCCmec type IV (class B mec (mecA, DmeC1, ugpQ) and ccrA-2, ccrB-2). The nine MRSA isolates belonged to ST59-MRSA-IV (6/9) and CC1-MRSA-VSC-Cfus (3/9) (class C mec (mecA, ugpQ) and ccrC and fusC (Q6GD50) and cassette chromosome recombinase (ccr) A-1, ccrB-1). Among 18 MR-CoNS identified (17 S. epidermidis and 1 S. saprophyticus), half harboured SCCmec type IV (8 S. epidermidis and the single S. saprophyticus). SCCmec types II, V and VII were identified in three, five and one of the remaining S. epidermidis isolates, respectively. Isolates from the one individual who exhibited nasal co-carriage of MRSA and MR-CoNS (S. epidermidis) both harboured SCCmec type IV (table 2).

In addition to the three CC1-MRSA-V isolates that carried SCCfus, the fusidic acid resistance genes fusC and fusB were identified in 28/128 (21.8%) and 2/128 (1.5%) of methicillin-susceptible S. aureus (MSSA) isolates, respectively. Ten of the 28 fusC-positive MSSA isolates belonged to CC1-MSSA-SCCfus, 11 were CC88-MSSA and 7 CC8-MSSA. All 10 CC1-MSSA-SCCfus isolates harboured a combination of SCCfus with the cer genes, ccrA-1 and ccrB-1. The two fusB-positive isolates belonged to CC5-MSSA and CC8-MSSA (table 2). Among MR-CoNS, 27.7% (5/18) S. epidermidis isolates carried fusC (two of them also carried cer genes ccrA-1 ccrB-1) and 50% fusB (9/18, eight S. epidermidis and the one S. saprophyticus).

### Statistical analyses

Fisher’s exact test was used to analyse categorical variables (prevalence of genes) using GraphPad QuickCalcs online software. The significance of differences between groups was expressed as two-tailed P values. P values of ≤0.05 were considered statistically significant.

### RESULTS

#### Nasal carriage of staphylococcal species and regional distribution

Thirty-one per cent (137/444) of students were positive for nasal carriage of *S. aureus* of whom 6.6% (9/137) were MRSA. Eighty-seven per cent (386/444) of students were positive for nasal carriage of CoNS. All students positive for *S. aureus* also carried *S. epidermidis*. Methicillin-resistant (MR)-CoNS were investigated only in those positive for nasal *S. aureus* in the student cohort and not in all those recruited. CoNS, coagulase-negative staphylococci; MRSA, methicillin-resistant *S. aureus*; MRSE, methicillin-resistant *S. epidermidis*; MRSH, methicillin-resistant *S. haemolyticus*; MRSS, methicillin-resistant *S. saprophyticus*.

#### Clonal lineages among *S. aureus* isolates

The ST or CC distribution among 137 *S. aureus* isolates is shown in figure 2. Isolates belonged to a variety of CCs with 46/137 (33.5%) assigned to internationally disseminated CC5, CC8, CC22, CC30, CC45. A further 24/137 (17.5%) isolates belonged to CC1, CC59, CC88 or CC398.

#### SCCmec types and fusidic acid resistance among *S. aureus* and CoNS

Of the 333 staphylococcal genes detected by the microarray, the two most prevalent antibiotic resistance genes among nasal staphylococci were those encoding resistance to β-lactams and fusidic acid. The most common SCCmec type among nasal MRSA (n=9) and MR-CoNS (n=18) was SCCmec type IV (class B mec (mecA, DmeC1, ugpQ) and ccrA-2, ccrB-2). The nine MRSA isolates belonged to ST59-MRSA-IV (6/9) and CC1-MRSA-VSC-Cfus (3/9) (class C mec (mecA, ugpQ) and ccrC and fusC (Q6GD50) and cassette chromosome recombinase (ccr) A-1, ccrB-1). Among 18 MR-CoNS identified (17 S. epidermidis and 1 S. saprophyticus), half harboured SCCmec type IV (8 S. epidermidis and the single S. saprophyticus). SCCmec types II, V and VII were identified in three, five and one of the remaining S. epidermidis isolates, respectively.

*CoNS were investigated only in those positive for nasal *S. aureus* in the student cohort.
Among methicillin-susceptible CoNS isolates, the \textit{fusC} and \textit{fusB} genes were identified in 20/119 (16.8%, 18 \textit{S. epidermidis} and two \textit{S. saprophyticus}) and 18/119 (15.1%, all \textit{S. epidermidis}), respectively. One participant had nasal co-carriage of \textit{fusC}-positive \textit{S. aureus} (CC88-MSSA) and CoNS (\textit{S. epidermidis}).

All SCC\textit{mec}-positive staphylococci were confirmed to have an MRSA/MR-CoNS phenotype. However, there was poor correlation between \textit{fusC/fusB} carriage and phenotypic fusidic acid resistance. Fusidic acid MICs for all \textit{fusC} or \textit{fusB}-positive \textit{S. aureus} and CoNS isolates are shown in table 3. Phenotypic fusidic acid resistance was confirmed (based on EUCAST breakpoints, MICs \(\geq 1\) µg/mL) in 23/32 (71.8%) \textit{S. aureus} and 20/38 (52.6%) CoNS nasal isolates harbouring either \textit{fusC} or \textit{fusB} (DNA microarray result confirmed by PCR). Eight nasal isolates (three \textit{S. aureus}, five \textit{S. epidermidis}) exhibited high-level fusidic acid resistance (MIC \(\geq 32\) µg/mL).

---

**Figure 1** Geographical origin of medical students recruited. The geographical areas of origin of 444 medical students recruited to the study are shown (dark grey bars). Of those recruited, 137 were confirmed nasal \textit{Staphylococcus aureus} and coagulase-negative staphylococci (CoNS) positive. The proportion of recruited students from each geographical origin with nasal \textit{S. aureus} carriage are also shown (light grey bars).

**Figure 2** Genotypic diversity of 137 \textit{Staphylococcus aureus} nasal isolates using DNA microarray analysis, including 128 methicillin-susceptible \textit{S. aureus} (MSSA) (dark grey bars) and 9 methicillin-resistant \textit{S. aureus} (MRSA) (light grey bars). Letter (a) indicates internationally disseminated clones into which staphylococcal cassette chromosome harbouring the \textit{mec} gene (SCC\textit{mec}) can integrate. CC, clonal complex; ST, sequence type.
Fusidic acid resistance was inducible in a further three *S. aureus* and seven *S. epidermidis* isolates following incubation with 0.01 µg/mL fusidic acid BHI agar.

Other notable antimicrobial resistance genes among nasal *S. aureus* and Cons

Apart from SCCmec element and *fus* genes, other antimicrobial genes detected among staphylococcal nasal flora were identified by DNA microarray. Tetracycline resistance genes, *tet(K) or tet(M)*, were detected in 13/137 (9.5%) of *S. aureus* isolates and 6/137 (4.3%) of the CoNS isolates. The quaternary ammonium compound resistance genes (*qacA/qacC*), encoding antiseptic resistance, were significantly more prevalent among CoNS isolates compared with *S. aureus* isolates (29/137 (21.2%) vs 2/137 (1.4%), *P*<0.0001). Significantly more CoNS than *S. aureus* isolates carried *ileS2* encoding high-level mupirocin resistance (11/137 (8%) vs 1/137 (0.72%), *P*<0.01). However, none of these genes were common to *S. aureus*/CoNS pairs recovered from the same individual. The *β*-lactamase genes were abundant among *S. aureus* and CoNS; *blaZ* was present in 101/137 (73.72%) *S. aureus* isolates and 92/137 (67.1%) CoNS isolate and in 74/137 (54%) of individuals, these genes were common to *S. aureus*/CoNS pairs from the same nares. A summary of the antibiotic resistance genes found among *S. aureus* and CoNS is shown in table 2. The staphylococcal isolates were negative for all other antibiotic resistance genes spotted on the microarray.

**Virulence genes among nasal *S. aureus* and CoNS**

A single isolate, CC30-MSSA, was positive for the Panton-Valentine leucocidin genes (*lukF/S-PV*). Among nasal staphylococci, ACME-arc was significantly associated with CoNS compared with *S. aureus* (44/137 (32.1%) vs 1/137 (0.72%), *P*<0.0001). The toxic shock syndrome toxin gene *tst1* was identified in 33/137 (24.1%) nasal *S. aureus* isolates. Unusually, DNA microarray identified *tst1* in two *S. epidermidis* isolates and this was confirmed by PCR. ACME-arc was common to *S. aureus*/CoNS pairs recovered from the nares in one individual only. One hundred and two (74.4%) *S. aureus* isolates encoded one or more...
enterotoxin genes. The enterotoxin gene cluster ((egc), containing seg, sei, SEM, sen, seo, seu) was the most prevalent (48/102, 47%) followed by seq/h (13/102, 12.7%) and sec/l (7/102, 6.8%). The staphylococcal isolates were negative for all other toxin genes spotted on the microarray.

**DISCUSSION**

Studies of staphylococcal carriage and epidemiology among the healthy population in the absence of significant antibiotic pressure are important in identifying the potential for pathogenic evolution. To our knowledge, this is the first study to coinvestigate CoNS and *S. aureus* when recovered together from the nares of healthy preclinical medical students. The species distribution of nasal colonising CoNS was similar to other studies, although the enrichment methods used here favoured *S. aureus* and *S. epidermidis* and may explain the low prevalence of other CoNS species. Our study revealed that, apart from the bba genes, which are abundant among staphylococci, the rates of co-carriage of antibiotic resistance genes in paired *S. aureus*/CoNS from the same individual were low in the community setting at <1%. Rates of simultaneous carriage of antimicrobial resistance among nasal staphylococci are likely to be higher under selective antibiotic pressure but few studies have investigated this among patients. One small study of hospitalised patients with nasal carriage of *S. aureus* and CoNS reported a rate of 12.5% patients carrying MRSA and MR-CoNS.15 However, the authors reported only two cases where simultaneous carriage of MR-CoNS and MRSA was detected and the strains involved carried different SCCmec types. Despite negligible detection of cospecies nasal carriage of these genes in medical students prior to healthcare exposure, based on antimicrobial resistance gene carriage by CoNS from this cohort, there is significant potential for mobilisation of genes to *S. aureus* that may enhance its pathogenic potential in the healthcare setting.

DNA microarray analyses revealed carriage of SCCmec, fusC, fusB, ileS2, qacA/qacC and ACME-arc among colonising nasal staphylococci in individuals with no previous healthcare exposure with greater prevalence among CoNS than *S. aureus*. This pattern among preclinical medical students supports CoNS as a reservoir with potential to subsequently accelerate antimicrobial resistance and pathogenicity among colonising *S. aureus* in clinical environments under antibiotic selective pressure.16 18 19

Despite considerable geographical distribution of the participants in this study, a *S. aureus* nasal carriage rate in the community of 30.8% was recorded. In this study, CC30, CC88 and CC8 were the most prevalent clones identified among nasal *S. aureus*. CC30 is among the internationally disseminated clones in which SCCmec has been acquired and is a successful colonising lineage, reported among HA and CA-MRSA. Among medical students, these MSSA isolates may therefore represent a significant pool for the uptake of SCCmec in a clinical setting. CC88 is frequently isolated in Australia but, in our study, the geographical background of isolates was mixed (including Middle East, Europe, South East Asia and Central America). CC8 is associated with MRSA infection and is globally disseminated.20 Although CC30, CC88 and CC8 were prevalent among community MSSA isolates in this study, among the relatively few MRSA recovered, none belonged to these CCs. Two CC/ST types detected among MRSA recovered from healthy medical students in this study were ST59-MRSA-IV and CC1-MRSA-V-SCCfusCST39 (Western Australian-MRSA-73) is a sporadic Australian strain and, apart from Panton Valentine Leukocidin (PVL) negativity, is indistinguishable from USA1000.21 In this study, the geographical background of these isolates was wide (Middle East, North America and South East Asia).

The identification of a significant reservoir of antibiotic resistance among medical students prior to healthcare exposure in subsequent clinical years highlights the need for effective infection prevention and control policies in relation to hand hygiene and surveillance. In the absence of antibiotic selective pressure, the colonising MRSA rate appears relatively stable and in this study was 2% (9/444), similar to rates reported elsewhere.22 However, a previous study among medical interns in China reported a nasal MRSA rate of 9.4% likely reflecting exposure to the healthcare environment.23 One study reported an increase in carriage rates of MR-CoNS from 14% among medical student preinternship to 29.28% among interns.24 Prevalence rates of MR-CoNS in recent community-based surveys are variable but rates of 16.5%19 and 17.2%25 are reported in similar cohorts to this study where, of those colonised with *S. aureus*, 13.1% carried MR-CoNS. SCCmec type IV, the smallest of the SCCmec elements, was the most prevalent type among MRSA and MR-CoNS here (66.6% and 50%). SCCmec type IV has been detected in approximately 40% of methicillin-resistant *S. epidermidis* identified in humans.26 However, in this study, SCCmec type V was also represented among MRSA and MR-CoNS. While only one individual was colonised with MRSA and MR-CoNS in this study (both SCCmec type IV), the preponderance of SCCmec IV element in nasal MRSA and MR-CoNS suggests the potential for mecA gene transfer among these species even in the absence of selective pressure. The small size of this element, which has a low fitness cost, may enhance its dissemination potential.27

Fusidic acid resistance among *S. aureus* from healthy carriers in nine European countries in 2014 was reported to be <10%.28 However, we found a prevalence of 22.6% of fusC/fusB genes among healthy carriers. Fusidic acid resistance appears to correlate with increased use of this agent. For example, in New Zealand, where it is used as a first-line empiric agent for topical treatment of impetigo, prevalence rates of resistance in community *S. aureus* isolates increased from 17% in 1999 to 29% in 2013.29 In Europe, fusidic acid is combined with β-lactams for the treatment of staphylococcal bacteraemia, endocarditis and osteomyelitis30 and is used widely in the community.
for skin and soft tissue infections. A 2010 study of fusidic acid resistance among _S. aureus_ clinical isolates showed Greece and Ireland to have the highest rates (32.5% and 19.9%). As highlighted here in the absence of significant antibiotic pressure in the community, it appears that this element is associated with MRSA and MSSA in the CCI background. This genetic platform, particularly when associated with SCCmec in a composite element (SCCmec V+SCCfus) may enable the transfer of multidrug resistance in a single transfer event. The use of fusidic acid is unregulated in some countries and hence it may be used inappropriately in a community setting (e.g., in short or discontinuous doses). Inappropriate use of fusidic acid may therefore favour coselection of methicillin resistance among _S. aureus_. In addition, in this study, 14/18 (77%) of MR-CoNS were positive for fusC or fusB. This association of resistances among the resident flora may provide further opportunity for dissemination of MRSA driven by fusidic acid selective pressure. Interestingly, a positive correlation between carriage of fusC/fusB and phenotypic resistance was observed in only 71.9% and 53.6% of _S. aureus_ and CoNS, respectively. However, induction of gene expression with fusidic acid preincubation gave better correlation (82.2% and 76.3% correlation).

There were limitations to this study, which included a single-centred, relatively small study. Some nasally abundant CoNS species, for example, _S. lugdunensis_ and _S. hominis_, were under-represented as the enrichment method favoured pathogenic staphylococci such as _S. aureus_ and _S. epidermidis_. CoNS was investigated only in those co-colonised with _S. aureus_ and therefore prevalence rates for genes among CoNS do not reflect the entire cohort. CCs and STs were determined only among _S. aureus_ as the high rate of genetic recombination among CoNS makes strain typing unreliable. Although the microarray system used is reported effective for staphylococcal species other than _S. aureus_, some gene targets may be heterologous among staphylococci leading to false negatives. The study design did not facilitate follow-up of this cohort during clinical training which may have revealed further changes in gene carriage among colonising staphylococci. However, the multinational origin of the student body in our institution facilitated analysis of a relatively broad geographic cohort in a single study and emphasises the role that importation plays in _S. aureus_ epidemiology. Unlike other studies of staphylococci in the healthy human nares, pairs of staphylococcal species originating from the same individual were investigated here for their resistance and virulence traits. These data support a low rate of transfer of antibiotic resistance between colonising staphylococcal species in the absence of healthcare contact. However, it is concerning that similar SCCmeC and SCCfusC types in addition to _ileS2, qacA/qacB_ and ACME are carried among CoNS and _S. aureus_ in healthy individuals who will have subsequent roles in healthcare provision. Given the increasing emergence of HA-MRSA with features of community strains, further mobilisation of these elements under selective antibiotic pressure may enhance the transmission and success of _S. aureus_ in the healthcare environment.
